Human trafficking victims often present to healthcare settings for treatment. Thus, healthcare professionals are in a unique position to be able to identify and assist victims. However, most healthcare professionals receive little to no formal training or education about human trafficking, and their perceptions of human trafficking are often formed through biased media depictions. This study sought to further understand healthcare professionals’ ability to identify victims of trafficking and biases healthcare professionals hold towards victims of trafficking based on victim demographic variables and trafficking type. Furthermore, this study explored the likelihood that healthcare professionals engage in prosocial behaviors towards victims of trafficking.
