Examining the Relationship Between Treatment Variables and Referral Processes on Probation Outcomes

Almost half of the justice-involved individuals on probation do not complete supervision successfully, highlighting the need to understand how different intervention types may increase supervision completion rates. Partnered with a local Texas probation department, primary data was collected on 738 justice-involved individuals to assess the impact of treatment-related factors on supervision termination. Looking at treatment as a general resource, this study assesses how treatment involvement affects probation termination and whether the degree of treatment participation or referral processes influences the likelihood of an individual successfully completing probation.
